ASSIGNMENT

There is a API (/bidconfig) REST call which updates every minute.

```
{
   "id": 1,
   "name": "Client ABC",
   "price": 12.50,
   "datetimes":{
          "updated":"2016-01-01T23:28:56.782Z",
          "last executed":"2016-04-01T23:29:11.045Z"
          }
   "tags": ["this", "that", "other"]
}
```

The responses can come out of order.

Create javascript which queries for updates in realtime.
User can call 2 functions:
          1) return an array sorted by last updated.
          2) return an array sorted by last executed.
The array size to be returned is an input function parameter.

Bonus: "Tag" is another input function parameter which can be a filter.

List your assumptions.
